# 6 Electrical Characteristics

## 6.1 Parameter Conditions

### 6.1.1 Minimum and Maximum Values

Unless otherwise specified the minimum and maximum values are guaranteed in the worst conditions of ambient temperature, supply voltage, and frequencies by tests in production on 100% of the devices with ambient temperature at  $T_a = 25^{\circ}\text{C}$  and  $T_a = T_{a\ max}$ .

Data based on characterization results, design simulation, and/or technology characteristics are indicated in the table footnotes and are not tested in production.

### 6.1.2 Typical Values

Unless otherwise specified, the typical data are based on  $T_a = 25^{\circ}\text{C}$ . They are given only as design guidelines.

### 6.1.3 Temperature Definitions

- Ambient Temperature— the temperature of the surrounding environment.
- Junction Temperature— the hottest temperature of the silicon chip inside the package.
- Absolute Maximum Junction Temperature— the temperature beyond which damage occurs to the device. The device may not function or meet expected performance at this temperature.
- Recommended Operating Temperature— the junction temperature at which the device operates continuously at the designated performance over the designed lifetime. The reliability of the device may be degraded if the device operates above this temperature. Some devices will not function electrically above this temperature.

## 6.2 Absolute Maximum Ratings

Absolute Maximum Ratings are those values beyond which damage to the device may occur. The following table specifies the absolute maximum ratings.

### CAUTION

Stresses beyond those listed under Table 6-1 may affect reliability or cause permanent damage to the device. These are stress ratings only. Functional operation of the device at these or any other conditions beyond those indicated under section 6.3 Recommended Operating Conditions is not implied. Exposure to absolute maximum rated conditions for extended periods may affect device reliability.

## 6.9 Clock Electrical Characteristics

### 6.9.1 Input Clock Requirements

#### 6.9.1.1 High-speed Crystal/Ceramic Resonator Characteristics

The high-speed external clock can be supplied with a 24 MHz crystal resonator (oscillation mode). The 24 MHz crystal resonator provides 24 MHz reference clock which is connected to the DXIN and DXOUT terminals.

Table 6-9 High-speed 24 MHz Crystal Requirements

Symbol	Parameter	Min	Typ	Max	Unit
$f_{X24M-IN}$	Crystal parallel resonance frequency	-	24	-	MHz
	Crystal frequency stability and tolerance at 25 °C <sup>(1)</sup>	-50	-	+50	ppm
	Oscillation mode	Fundamental			-
$C_0$	Shunt capacitance <sup>(2)</sup>	-	6.5	-	pF

1. The 50 ppm frequency stability and tolerance can meet the requirement of T527. We recommend selecting 20 ppm crystal devices. If the REFCLK-OUT (24 MHz fanout) is used for Wi-Fi chip, the crystal uses the recommended specification or the specified model for Wi-Fi chip.
2. The 6.5 pF is only a simulation value. The crystal shunt capacitance ( $C_0$ ) is given by the crystal manufacturer.

Table 6-10 Crystal Circuit Parameters

Symbol	Parameter
$C_1$	$C_1$ capacitance
$C_2$	$C_2$ capacitance
$C_L$	Equivalent load capacitance, specified by the crystal manufacturer
$C_0$	Crystal shunt capacitance, specified by the crystal manufacturer
$C_{shunt}$	Total shunt capacitance

Frequency stability mainly requires that the total load capacitance ( $C_L$ ) be constant. The crystal manufacturer typically specifies a total load capacitance which is the series combination of  $C_1$ ,  $C_2$ , and  $C_{\text{shunt}}$ .

The total load capacitance is  $C_L = [(C_1 * C_2)/(C_1 + C_2)] + C_{\text{shunt}}$ .

- $C_1$  and  $C_2$  represent the total capacitance of the respective PCB trace, load capacitor, and other components (excluding the crystal) connected to each crystal terminal.  $C_1$  and  $C_2$  are usually the same size.
- $C_{\text{shunt}}$  is the crystal shunt capacitance ( $C_0$ ) plus any mutual capacitance ( $C_{\text{pkg}} + C_{\text{PCB}}$ ) seen across the DXIN and DXOUT signals.

In the application, the crystal resonator and the load capacitors must be placed close to the oscillator pins in order to minimize output distortion and the startup stabilization time. Refer to the crystal resonator manufacturer for more details on the resonator characteristics.

#### 6.9.1.2 Low-speed Crystal/Ceramic Resonator Characteristics

The T527 contains an RC oscillation circuit that generates a 32.768 kHz clock, meanwhile, the DCXO module can calibrate the RC oscillation circuit regularly. If the product does not have a high requirement for the accuracy of the system clock, the external 32.768 kHz crystal circuit can be omitted and the internal RC oscillation circuit can be adopted, meanwhile, the relevant clock configuration needs to be turned on by the software.

The T527 also can connect to a 32.768 kHz crystal resonator (oscillation mode). The 32.768 kHz crystal resonator provides 32.768 kHz reference clock which is connected to the X32KIN and X32KOUT terminals. In the application, the crystal resonator and the load capacitors must be placed close to the oscillator pins to minimize output distortion and the startup stabilization time. Refer to the crystal resonator manufacturer for more details on the resonator characteristics.

Table 6-11 Low-speed 32.768 kHz Crystal Circuit Characteristics

Symbol	Parameter	Min	Typ	Max	Unit
$f_{X32K-IN}$	Crystal parallel resonance frequency	-	32.768	-	kHz
	Crystal frequency stability and tolerance at 25 °C <sup>(1)</sup>	-	-	-	ppm
	Oscillation mode	Fundamental			-
$C_0$	Shunt capacitance <sup>(2)</sup>	-	1.1	-	pF

The T527 has no requirement for the frequency stability and tolerance of 32.768 kHz crystal. If the actual product has requirement for the accuracy of timing function, the 20 ppm stability and tolerance is recommended.

The 1.1 pF is only a simulation value. The crystal shunt capacitance ( $C_0$ ) is given by the crystal manufacturer.

# 7 Temperature and Thermal Characteristics

## 7.1 Temperature

The following tables describe the temperature of T527.

**Table 7-1 Operating and Storage Temperature**

Symbol	Parameter	Min	Max	Unit
T <sub>a</sub>	Ambient Operating Temperature	-40	85	°C
T <sub>STG</sub>	Storage Temperature	-40	150	°C

**Table 7-2 Junction Temperature**

Chip	Working junction temperature (T <sub>j</sub> )		Destructive Junction Temperature <sup>(2)</sup>	Unit
	Min	Max <sup>(1)</sup>		
T527	-40	115	125	°C

(1) The junction temperature of the chip should be less than or equal to this value under normal operating conditions.

(2) The junction temperature of chip should not be more than this value under any conditions.

## 7.2 Package Thermal Characteristics

The maximum chip junction temperature (T<sub>j</sub> max) must never exceed the values given in Table 7-2 Junction Temperature.

Failure to maintain a junction temperature within the range specified reduces operating lifetime, reliability, and performance, and may cause irreversible damage to the system. It is useful to calculate the exact power consumption and junction temperature to determine which the temperature will be best suited to the application. Therefore, the product should include thermal analysis and thermal design to ensure the operating junction temperature of the device is within functional limits.

The following tables show the thermal resistance characteristics of the T527. These data are based on JEDEC JESD51 standard, because the actual system design and temperature could be different from JEDEC JESD51, these simulating data are a reference only and may not represent actual use-case values, please prevail in the actual application condition test.

## 9.2 Storage

Reliability is affected if any condition specified in Section 8.2.2 and Section 8.2.3 has been exceeded.

### 9.2.1 Moisture Sensitivity Level (MSL)

A package's MSL indicates its ability to withstand exposure after it is removed from its shipment bag, a low MSL device sample can be exposed on the factory floor longer than a high MSL device sample. Table 9-3 defines all MSL.

**Table 9-3 MSL Summary**

MSL	Out-of-bag floor life	Comments
1	Unlimited	≤30°C / 85%RH
2	1 year	≤30°C / 60%RH
2a	4 weeks	≤30°C / 60%RH
3	168 hours	≤30°C / 60%RH
4	72 hours	≤30°C / 60%RH
5	48 hours	≤30°C / 60%RH
5a	24 hours	≤30°C / 60%RH
6	Time on Label (TOL)	≤30°C / 60%RH

#### NOTE

The T527 device samples are classified as MSL3.

### 9.2.2 Bagged Storage Conditions

The following table defines the shelf life of the T527 device samples.

**Table 9-4 Bagged Storage Conditions**

Packing mode	Vacuum packing
Storage temperature	20–26°C
Storage humidity	40%–60%RH
Shelf life	12 months

### 9.2.3 Out-of-bag Duration

It is defined by the device MSL rating. The out-of-bag duration of the T527 is as follows.

**Table 9-5 Out-of-bag Duration**

<b>Storage temperature</b>	20–26°C
<b>Storage humidity</b>	40%–60%RH
<b>Moisture sensitive level (MSL)</b>	3
<b>Floor life</b>	168 hours

For no mention of storage rules in this document, refer to the latest *IPC/JEDEC J-STD-020C*.

### 9.3 Baking

It is not necessary to bake the T527 if the conditions specified in Section 8.2.2 and Section 8.2.3 have not been exceeded. It is necessary to bake the R528 if any condition specified in Section 8.2.2 and Section 8.2.3 has been exceeded.

It is necessary to bake the T527 if the storage humidity condition has been exceeded, we recommend that the device sample removed from its shipment bag for more than 2 days shall be baked to guarantee production.

Baking conditions: 125°C, 8 hours, nitrogen protection. Note that the baking should not exceed 1 time due to a risk of deformation.

## 10 Reflow Profile

All Allwinner chips provided for clients are lead-free RoHS-compliant products.

The reflow profile recommended in this document is a lead-free reflow profile that is suitable for pure lead-free technology of lead-free solder paste. If customers need to use lead solder paste, contact Allwinner FAE.

The following figure shows the appropriate reflow profile.

Figure 10-1 Lead-free Reflow Profile

Table 10-1 Lead-free Reflow Profile Conditions

QTI typical SMT reflow profile conditions (for reference only)		
	Step	Reflow condition
Environment	N2 purge reflow usage (yes/no)	Yes, N2 purge used
	If yes, O2 ppm level	O2 < 1500 ppm
A	Preheat ramp up temperature range	25 °C -> 150 °C
B	Preheat ramp up rate	1.5–2.5 °C/s
C	Soak temperature range	150 °C -> 190 °C
D	Soak time	80–110 s
E	Liquidus temperature	217°C
F	Time above liquidus	60–90 s
G	Peak temperature	240–250 °C
H	Cool down temperature rate	≤4°C/s

The method of measuring the reflow soldering process is as follows.

Fix the thermocouple probe of the temperature measuring line at the connection point between the pin (solderable end) of the packaged device and the pad by using high-temperature solder wire or high-temperature tape, fix the packaged device at the pad by using high-temperature tape or other methods, and cover over the thermocouple probe. See Figure 10-2.

Figure 10-2 Measuring the Reflow Soldering Process

NOTE

To measure the temperature of the QFP-packaged chip, place the temperature probe directly at the pin.

If possible, the more accurate measuring way is to drill the packaged device, or drill the PCB, and fix the thermocouple probe through the drilled hole at the pad.

# 11 FT/QA/QC Test

## 11.1 FT Test

FT test is the finished product testing after the chip is packaged, and it is a functional test of all modules for each produced chip.

## 11.2 QA Test

QA test is a system-level sampling test for good-quality chips. According to the application level of the chip, a certain percentage of good-quality chips are selected for system-level testing to make the chip work in a typical application scenario, and judge whether the chip works normally in this scenario.

## 11.3 QC Test

QC test is a module-level sampling test for good-quality chips. According to the chip application level, a certain percentage of good-quality chips are selected for module-level functional testing to monitor whether the chip production process is normal.
